**Amendments to the Abstract:** 

Please replace the Abstract with the following new Abstract:

A positive grid for lead-acid batteries made from calcium-tin-silver lead-based alloys.

The grid is made by casting an alloy strip and then rolling the strip at a temperature between

about the solvus temperature and the peritic temperature of the alloy, quenching the rolled strip,

then, preferably, heat aging at a temperature of 200 °F to 500 °F and fabricating the positive grid.

The alloy strip comprises an  $\alpha$ -lead rich phase with a face-centered cubic structure.
